

The High Dividend Yield Return Advantage:
An Examination of Empirical Data Associating Investment in
High Dividend Yield Securities with Attractive Returns Over
Long Measurement Periods.

“The deepest sin against the human mind is to believe things without evidence”.

-T.H. Huxley

In the pages that follow, we set forth a number of studies, largely from academia, analyzing the importance of dividends, and the association of high dividend yields with attractive investment returns over long measurement periods. You may be familiar with our prior booklet, *What Has Worked In Investing*, where we provided an anthology of studies which empirically identified a return advantage for value-oriented investment characteristics. In the same spirit, we attempt to examine what some in our industry have referred to as the “yield effect”; i.e., the correlation of high dividend yields to attractive rates of return over long measurement periods. Much has been written about dividends, and what is contained herein is not meant to be an exhaustive analysis, but rather a sampling of studies examining the impact of dividends on investment returns. We hope it will provide you with added insight and confidence, as it did us, in pursuing a yield-oriented investment strategy.

WHY DIVIDENDS ARE IMPORTANT

- Over the long term, the return from dividends has been a significant contributor to the total returns produced by equity securities.
- There is an abundance of empirical evidence which suggests that portfolios consisting of higher dividend yielding securities produce returns that are attractive relative to lower-yielding portfolios and to overall stock market returns over long measurement periods.
- Stocks with high and apparent sustainable dividend yields that are competitive with high quality bond yields may be more resistant to a decline in price than lower-yielding securities because the stock is in effect “yield supported”. The reinvestment of dividends during stock market declines has also been shown to lessen the time necessary to recoup portfolio losses.
- The ability to pay cash dividends is a positive factor in assessing the underlying health of a company and the quality of its earnings. This is particularly pertinent in light of the complexity of corporate accounting and numerous recent examples of “earnings management”, including occasionally fraudulent earnings manipulation.
- For years and years, U.S. tax policy disadvantaged dividends, applying high ordinary income tax rates to the dividends paid to investors. This changed with the enactment of the 2003 Jobs and Growth Tax Relief Reconciliation Act. For individuals, qualified dividends are now taxed at the same favorable rates as long-term capital gains (15%).

DIVIDENDS AND THEIR CONTRIBUTION TO INVESTMENT RETURNS

Reinvested Dividends Have Been the Dominant Contributor to Long-Term Returns on Equity Securities

In their book, *Triumph of the Optimists: 101 Years of Global Investment Returns* Princeton University Press (2002), Elroy Dimson, Paul Marsh, and Mike Staunton examined the respective contributions to returns provided by capital gains and dividends from 1900 to 2000. They discovered that while year-to-year performance was driven by capital appreciation, long-term returns were largely driven by reinvested dividends. In the chart below, they showed the cumulative contribution to return of capital gains and dividends in both the U.S. and the U.K. from 1900 to 2000. Over 101 years, they found that a market-oriented portfolio, which included reinvested dividends, would have generated nearly 85 times the wealth generated by the same portfolio relying solely on capital gains. This wealth accumulation would, of course, have been lower if dividends were not assumed to have been reinvested.

Figure 11-2: Impact of reinvested dividends on cumulative US and UK equity returns, 1900–2000

Dividends Have Not Only Dwarfed Inflation, Growth and Changing Valuation Levels Individually, but They Have Also Dwarfed the Combined Importance of Inflation, Growth and Changing Valuation Levels

In an editorial in the *Financial Analysts Journal* in 2003, entitled *Dividends and the Three Dwarfs*, Robert D. Arnott examined the various components of equity returns for the 200 years ending in 2002. He concluded that dividends were far and away the main source of the real return one would expect from stocks, dwarfing the other constituents: inflation, rising valuations, and growth in dividends. In the chart below, Arnott shows the contribution to total return for each of these constituents for the period 1802 to 2002. The total annualized return for the period of 7.9% consisted of a 5% return from dividends, a 1.4% return from inflation, a 0.6% return from rising valuation levels, and a 0.8% return from real growth in dividends. He concludes that "... unless corporate managers can provide sharply higher real growth in earnings, dividends are the main source of the real return we expect from stocks."

HIGH DIVIDEND YIELD SECURITIES HAVE PRODUCED ATTRACTIVE RETURNS OVER TIME

The Rejection of a Tax-Based Explanation for the Premium Returns of High Yield Securities in the U.K.

In a paper published in the **Journal of Financial Economics** in 1979, entitled *The Effect of Personal Taxes and Dividends on Capital Asset Prices*, Robert Litzenberg of Stanford University and Krishna Ramaswamy of Bell Labs, discovered a strong correlation between expected pre-tax returns and dividend yields of common stocks. They reasoned that investors would demand superior pre-tax returns from dividend paying securities to compensate for the higher tax rates applied against their dividend income streams. Their data, which was supplied by the Center for Research in Security Prices at the University of Chicago (CRSP), indicated that "... for every dollar increase in return in the form of dividends, investors required an additional 23 cents in before-tax return."

In a later paper, entitled *Taxes, Dividend Yields and Returns in the UK Equity Market*, **Journal of Banking & Finance** (1998), Gareth Morgan and Stephen Thomas of the University of Southampton also found a return premium associated with higher dividend yield securities, but their data rejected a tax-based explanation since in the UK dividend income is taxed more favorably than capital gains. Using data from the London Share Price Database (LSPD), they examined the relationship between dividend yields and stock returns from 1975 through 1993 in the UK. Database companies were ranked by dividend yield at the end of each month and divided into six groups, including a zero dividend group (companies that did not pay dividends). In the table below from page 12 of their study, Messrs. Morgan and Thomas find a strong correlation between the size of the dividend yield and the average monthly return.

Table 1
Portfolios ranked by dividend yield using monthly data 1975-1993

Dividend Yield Portfolio	Average Monthly Return (%) ^a	Average Dividend Yield	Average Market Value of Equity ^b	Market Model Estimate of α	Market Model Estimate of β
1 (Highest)	2.51 (5.62)	11.07	136.53	0.53 ^c	0.95
2	2.23 (5.22)	7.69	207.27	0.18 ^c	1.01
3	1.98 (5.16)	5.93	205.68	0.01	0.95
4	1.86 (4.90)	4.31	183.93	-0.01	0.94
5 (Lowest)	1.56 (4.93)	2.25	133.21	-0.44 ^c	0.97
6 (Zero)	2.06 (6.58)	0.00	33.66	-0.17	1.16

F-test ^e	0.85				

Source: *Taxes, Dividend Yields and Returns in the UK Equity Market*, Gareth Morgan and Stephen Thomas, **Journal of Banking & Finance**, 1998, p. 410

^a Standard deviations are in parentheses. Standard deviation is the statistical measurement of dispersion about an average, which depicts how widely a stock or portfolio's returns varied over a certain period of time. Investors use the standard deviation of historical performance to try to predict the range of returns that is most likely for a given investment. When a stock or portfolio has a high standard deviation, the predicted range of performance is wide, implying greater volatility.

^b Average market value of equity calculated from annual data, expressed in millions of pounds.

^c Indicates a t -statistic giving a 95% probability of significance.

^d t -test (452 degrees of freedom) of null hypothesis that the mean return to portfolio 1 equals the mean return to portfolio 5.

^e F-statistic (distributed (5.13356)) tests the null hypothesis that average returns are equal for each dividend yield group.

Please note that the information in the chart above reflects past performance and is not intended to predict or project future investment results.

High Dividend Yield in the United Kingdom

In a paper entitled *Stock Market Anomalies: A Reassessment Based on the U.K. Evidence*, **Journal of Banking and Finance**, December 1989, Professor Mario Levis, at The School of Management, University of Bath, United Kingdom, examined a number of anomalies in stock price behavior of firms on the London Stock Exchange, including the correlation between dividend yield and investment returns. In a subsequent paper, entitled *Market Anomalies: A Mirage or a Bona Fide Way to Enhance Returns?*, Michael Lenhoff of CapelCure Myers Capital Management, used data largely derived from Professor Levis' study to illustrate a strong positive relationship between dividend yield and attractive rates of return. Using a sample of 4,413 companies, all of which were listed on the London Stock Exchange during January 1955 through December 1988, Lenhoff ranked these listed companies each year according to dividend yield and sorted the companies into deciles. The 34-year compounded annual investment returns and cumulative values of an assumed £1 million initial investment in each of the ten groups is shown in the following table, along with descriptive information concerning each group's average dividend yield and market capitalization.

In his study, there was almost a perfect correlation in the decile returns between higher dividend yields and higher annualized returns. The top decile, in terms of high yield, produced an average annualized return over 34 years of 19.3% versus 13.0% for the Financial Times Actuaries All Share Index.

Investment Results of U.K. Companies According to Dividend Yields, January 1955 through December 1988

Dividend Yield Group	Yield	Annual Investment Return	Cumulative Value of £1 Million in Jan 1955 at Dec 1988	Average Market Cap (£ million)
1	13.6%	19.3%	£403.4	£283.4
2	10.9	17.7	254.9	278.5
3	8.7	16.8	196.4	337.2
4	7.4	16.0	155.4	266.4
5	6.4	15.4	130.3	223.1
6	5.5	14.1	88.7	206.5
7	4.7	12.4	53.2	112.1
8	4.0	11.9	45.7	95.4
9	3.1	11.5	40.5	94.4
10	1.4	13.8	81.1	74.6
Financial Times-Actuaries All Share Index	5.3%	13.0%	£63.8	£503.5

Please note that the information in the chart above reflects past performance and is not intended to predict or project future investment results.

Mr. Lenhoff further noted that, "... there is a near perfect inverse correlation between the ratio of price-to-net asset value [i.e., book value] for the U.K. equity market and yield. When price stands significantly at a discount [premium] to the net asset value, the yield available from U.K. plc is significantly above [below] the long run range." Mr. Lenhoff also went on to observe that the price/earnings ratios of high dividend yield companies are usually low in relation to the price/earnings ratio of the entire stock market and that the high yield companies are often takeover candidates.

While it is not the case in all instances, in Tweedy, Browne's experience, high dividend yields are often associated with stocks selling at low prices in relation to earnings, book value and specific appraisals of the value that shareholders would receive in a sale of the entire company based upon valuations of similar businesses in corporate transactions.

Companies throughout the World: High Dividend Yield

In *The Importance of Dividend Yields in Country Selection*, **The Journal of Portfolio Management**, Winter 1991, A. Michael Keppler examined the relationship between dividend yield and investment returns for companies throughout the world. Mr. Keppler's study assumed an equal-weighted investment each quarter in each of the following eighteen Morgan Stanley Capital International equity indexes over the 20-year period, December 31, 1969 through December 31, 1989: Australia, Austria, Belgium, Canada, Denmark, France, Germany, Hong Kong, Italy, Japan, The Netherlands, Norway, Singapore/Malaysia, Spain, Sweden, Switzerland, the United Kingdom, and the United States. Each quarter, the country indexes were ranked according to dividend yield and sorted into four quartiles. The total investment return was measured for each of the four quartile groups over the subsequent three months.

The study indicated that the most profitable strategy was investment in the highest yield quartile. The compound annual investment return for the countries with the highest yielding stocks was 18.49% in local currencies (and 19.08% in U.S. dollars) over the 20-year period, December 31, 1969 through December 31, 1989. The least profitable strategy was investment in the lowest yield quartile, which produced a 5.74% compound annual return in local currency (and 10.31% in U.S. dollars). The Morgan Stanley Capital International World Index return over the same period was 12.14% in local currency (and 13.26% in U.S. dollars). On an equal-weighted basis, the MSCI World Index was up 15.5% for the period in local currency.

**Compound Annual Returns (in local currencies) based on various
dividend yield strategies and the MSCI World Index
December 1969 - December 1989**

Source: *The Importance of Dividend Yields in Country Selection*, A. Michael Keppler, **The Journal of Portfolio Management**, Winter 1991

- * MSCI World Index (equally weighted) in local currency; on a capitalization-weighted basis, the MSCI World Index returned 12.14% in local currency.
- Strategies based on yield:
 - (1) Invest in only top quartile yielding country indices
 - (2) Invest in the top two quartiles based on yield
 - (3) Invest in the top three highest yielding quartiles
 - (4) Invest in the bottom three quartiles based on yield
 - (5) Invest in the bottom two quartiles based on yield
 - (6) Invest in only the lowest yielding quartile.

Please note that the information in the chart above reflects past performance and is not intended to predict or project future investment results.

Dogs of the Dow

The “Dogs of the Dow” is a yield-oriented strategy first popularized by Michael B. O’Higgins with John Downes in their book, *Beating the Dow* (1991, revised and updated 2000). O’Higgins discovered that by investing in the 10 highest yielding securities in the Dow Jones Industrial Average of 30 industrial companies, and rebalancing annually, one could substantially outperform the average itself. Specifically, O’Higgins found that over the 26-year period from 1973 to 1998, a portfolio consisting of the ten highest yielding securities in the Dow Jones Industrial Average produced a return of 17.9% annually, as compared to 13.0% for the DJIA. This strategy has become very popular over the years with brokerage firms and retail investors. O’Higgins felt strongly that his high dividend yield strategy was, in essence, a contrarian approach emphasizing those components of the Dow Jones Industrial Average that were currently out of favor as reflected in higher dividend yields.

Total Return* Comparisons

Year	Ten Highest-Yield	DJIA
1973	3.9%	-13.1%
1974	-1.3	-23.1
1975	55.9	44.4
1976	34.8	22.7

The Returns from High Dividend Yield Stocks Trumped their Low Dividend Yield Counterparts in the U.S. over the 1926-2000 Period

The chart below, taken from Dimson, Marsh and Staunton’s, *Triumph of the Optimists: 101 Years of Global Investment Returns*, shows the cumulative returns since 1926 of U.S. stocks that rank each year in the highest or lowest-yielding 30% of companies, and compares the two groups to the CRSP value-weighted equity index. Higher dividend yield stocks outperformed their lower-yielding counterparts and the index by 180 and 160 basis points annualized from year-end 1926 to year-end 2000. (A basis point is one-hundredth of a percentage point.) This translated into 2.29 times the wealth generated by the lower-yielding stocks.

Performance of High Dividend Yield Stocks of the S&P 500, 1957-2002

In a more recent study, *The Future for Investors*, Crown Business, 2005, Jeremy Siegel, the noted finance professor at the University of Pennsylvania, examined the performance of the component stocks of the Standard and Poor’s 500 Stock Index, ranked by dividend yield from 1957 to 2002. In his study, on December 31 of each year, the S&P 500 stocks were sorted into five quintiles ranked by dividend yield. He then calculated the returns of the stocks and quintiles over the next year, re-sorting at year-end. He found that better results were directly correlated with higher dividend yields. The highest yielding quintile (top 20% of S&P 500 based on yield) produced an annualized return of 14.27% versus an annualized return of 11.18% for the S&P 500 Index, which resulted in three times the wealth accumulation of the index.

FIGURE 9.2: CUMULATIVE RETURNS TO S&P 500 SORTED BY DIVIDEND YIELD (SOURCE: COMPUSTAT®)

Source: *The Future for Investors*, Jeremy J. Siegel, Crown Business, 2005, p.128

Please note that the information in the chart above reflects past performance and is not intended to predict or project future investment results.

Professor Siegel also coined the terms “bear market protector” and “return accelerator” to describe how dividend reinvestment during stock market declines can dramatically lessen the time necessary to recoup portfolio losses.

Stocks Ranked by Low Price in Relation to Dividends Produced Attractive Returns Over the 1970-1996 Period

In his study contained in the book, *Contrarian Investment Strategies: The Next Generation*, published in 1998, David Dreman, a well-known practitioner of low price-to-earnings value investing, analyzed the annual returns of price-to-dividend strategies using data derived from the Compustat 1500 (largest 1500 publicly traded companies) for the 27-year period ending December 31, 1996. As indicated in the table below, he found that the highest yielding top two quintiles of the Compustat 1500 stock universe — as reflected by low prices in relation to dividends — outperformed the market by 1.2% and 2.6% annualized, respectively, and outperformed the stocks with low-to-no yield by 3.9% and 5.3% annually.

High Dividend Yield Stocks in the U.S. Have Produced More Return with Less Risk than their Low-Yield Counterparts

In a recent 36-year study conducted by Lehman Brothers equity research group in September 2005, high dividend yield stocks were found to have produced more return with less risk than their low-yield counterparts. The Lehman analysts studied the one thousand largest of U.S. firms ranked by market capitalization, and rebalanced these securities quarterly, starting in January 1970. They found that the top-yielding quintile produced a 13.7% equal-weighted total return per year with a 15.5% standard deviation of return. The bottom-yielding quintile, in comparison, returned 9.0% with a 29.1% standard deviation.*

Figure 1: Annualized Return and Standard Deviation of Highest (Q1) to Lowest (Q5) Dividend-Yielding Quintiles Since December 1969

* Standard deviation is the statistical measurement of dispersion about an average, which depicts how widely a stock or portfolio's returns varied over a certain period of time. Investors use the standard deviation of historical performance to try to predict the range of returns that is most likely for a given investment. When a stock or portfolio has a high standard deviation, the predicted range of performance is wide, implying greater volatility.

High Dividend Yield Stocks Generally Outperform those with Lower Yields – However, the Best Returns Have Not Come from those with the Highest Yields – Higher Yields Coupled with Low Payout Ratios Have Produced the Best Returns

In a recent equity research paper, entitled *High Yield, Low Payout*, Credit Suisse Quantitative Equity Research, August 15, 2006, Credit Suisse analysts Pankaj N. Patel, Souheang Yao and Heath Barefoot found that while high dividend yield stocks did indeed outperform their lower yield counterparts, the highest yield stocks were not the overall leaders in terms of return. They ran a simulation of a dividend strategy from January 1980 to June 2006, limiting their universe to stocks within the S&P 500. They created equal-weighted decile baskets based on dividend yields as of each month-end. Over the 26-year period, they found that stocks with higher dividend yields generally outperformed those with low dividend yields, but the highest yield decile did not produce the best overall return. As their chart below indicates, deciles 8 and 9 outperformed decile 10, the highest yield decile.

Exhibit 7: Dividend Yield Strategy

Equal-weighted decile performance from January 1980 to July 2006 (universe: S&P 500)

Source: *High Yield, Low Payout* by Credit Suisse Quantitative Equity Research, August 15, 2006, p.5

Source: Credit Suisse Quantitative Equity Research.

Please note that the information in the chart above reflects past performance and is not intended to predict or project future investment results.

In addition, they found within the higher dividend yield universe a direct correlation between low payout ratios and higher returns. Specifically, they created three dividend yield baskets ranked by yield; i.e., high yield, low yield and no yield. Then, within each of these baskets they categorized stocks based on payout ratio; i.e., high, medium and low. Equal-weighted portfolios of these baskets were created based on dividend yields and payout ratios as of each quarter end for the period January 1990 to June 2006; i.e., high yield, low payout; low yield, low payout; low yield, high payout, etc. The stocks used were those of the S&P 500. As you can see from the chart that follows, the basket with the highest yields combined with low payout ratios produced the best returns. The high yield, low

payout portfolio bucket generated an annualized return for the period of 19.2% versus 11.16% for the S&P 500. Arithmetically, the lower the payout ratio associated with a given level of dividend yield, the higher the earnings yield for the company, and the cheaper the stock based on price-to-earnings multiples: The high yield, low payout stocks that produced the better returns were priced at low ratios of price-to-earnings, and as a corollary, at high ratios of earnings-to-price; i.e., earnings yield.

THE DEFENSIVE NATURE OF HIGH DIVIDEND YIELDS DURING MARKET DECLINES

High Dividend Yield Stocks Outperformed other Value Strategies and the Market on Average in Down Market Quarters from 1970-1996

In another study, entitled *When The Bear Grows: Bear Market Returns 1970-1996*, contained in **Contrarian Investment Strategies: The Next Generation**, David Dreman, in collaboration with Eric Lufkin, examined the effectiveness of contrarian value strategies in down market quarters for the 27 years ended December 31, 1996. The Compustat 1500 database (1500 largest publicly traded stocks) was used, and the performance of four value strategies — low price-to-earnings, low price-to-book value, low price-to-cash flow, and high dividend yields — were measured and averaged for all down quarters and then compared to the index itself for the 27-year period. All of the value strategies outperformed the market, with the high dividend strategy (low price-to-dividend) performing the best of all the value strategies, declining on average only 3.8%, or roughly one-half as much as the market.

Figure 7-5
When the Bear Grows
Bear Market Returns 1970 - 1996

Source: *Contrarian Investment Strategies: The Next Generation*, David Dreman, Simon & Schuster, 1998, p. 157

Please note that the information in the chart above reflects past performance and is not intended to predict or project future investment results.

When both the up and down quarters were considered over the full 27 years, again, all of the value strategies outperformed the market, but the price-to-dividend strategy trailed the other strategies somewhat. For the full 27-year period, through both up and down quarters, the price-to-dividend strategy produced an annualized return of 16.1% versus 14.9% for the market.

Conclusions

In the preceding pages, we examined a number of papers and empirical studies from academics, economists and investment professionals that analyzed the relationship between dividend yield and investment returns over time. The following conclusions can be drawn:

1. Over the last 100 plus years, an investment in a market-oriented portfolio that included, most importantly, reinvested dividends, would have produced 85 times the wealth generated by the same portfolio relying solely on capital gains.
2. There is substantial empirical evidence to support a direct correlation between high dividend yields and attractive total returns.
3. Three of the studies found that the best returns were not produced by the highest yielding decile or quintile, but rather by the next highest yielding one or two deciles, or the next highest yielding quintile.
4. At least one study demonstrated that the returns associated with market-beating high dividend yield stocks were also less volatile in terms of the standard deviation of returns.
5. In several of the studies, high dividend yield stocks also sold at low ratios of price-to-book value and/or price-to-earnings.
6. The return advantages of high dividend yield stocks held for equity securities in both the U.S. and throughout the world.
7. At least one study found that high dividend yield stocks outperformed other value strategies as well as the overall stock market return in declining markets.
8. The reinvestment of dividends from high-yield stocks can dramatically shorten the time necessary to recoup losses in declining markets.

It seems clear, at least from the studies contained herein, that stocks with high dividend yields have enjoyed interesting return advantages over their lower yielding counterparts. As to why this is the case, we can only surmise. Some observers, such as Michael Lenhoff of Capel Cure Myers Capital Management, suggest that a multiple characteristic value effect may, at least in part, account for this return anomaly. Lenhoff noted that the high dividend yield stocks in his study also sold at relatively low ratios of price-to-book value and price-to-earnings. In various empirical studies, stocks priced low in relation to earnings and/or book value have produced above-market returns; i.e., a “value effect”. Similarly, the Credit Suisse high yield, low payout study found that high dividend yield stocks priced at low multiples of price-to-earnings performed best. Also, in Tweedy, Browne’s experience, high dividend yield stocks often possess one or more value characteristics such as low price-to-earnings ratios, low price-to-book value ratios, or relatively low prices in relation to specific appraisals of the value that shareholders would receive in a sale of the entire company based upon valuations of similar businesses in corporate transactions.

The studies contained herein did not present information or conclusions concerning the pattern, sequence, or consistency of high dividend investment returns over short subset periods of time, which comprised longer measurement periods. Questions such as whether the excess returns from stocks with high dividend yields were generated in 50% of the years, or 30% of the years, or in a several year “run” of outperformance followed by several “dry” years of underperformance were not addressed. While some studies point in the direction of lower variability of returns for high dividend stocks, no effort was made in this paper to assess the impact of potential sector concentration on the historical annual returns of high dividend yield stocks.

As the studies in this paper have indicated, there have been recurring patterns of investment success for high dividend yield stocks over very long periods of time. We believe that helpful perspective and, occasionally, patience and perseverance, are provided by an awareness of these patterns.

Endnotes

Investing in foreign securities involves additional risks beyond the risks of investing in U.S. securities markets. These risks include currency fluctuations; political uncertainty; different accounting and financial standards; different regulatory environments; and different market and economic factors in various non-U.S. countries. In addition, the securities of small, less well known companies may be more volatile than those of larger companies. Please refer to the Fund's prospectus for a description of risk factors associated with investments in securities that may be held by the Fund.

The studies presented herein provide a review of the relative past performance of selected securities associated with high dividend yields and various indices. The investment returns presented in the studies represent past performance and should not be considered indicative or representative of the future performance of the Tweedy, Browne Worldwide High Dividend Yield Value Fund, nor should it be inferred that the future performance of the Tweedy, Browne Worldwide High Dividend Yield Value Fund will equal or exceed the performance set forth in the studies. Although we are not aware of their existence, there may be studies that exist that contradict the conclusions of the studies presented herein.

This material is not intended to address every situation, nor is it intended as a substitute for the legal, accounting or financial counsel of your professional advisors, especially with respect to the tax treatment of dividends and your individual circumstances.

Investors should bear in mind that as with any wealth building investment strategy, potential future wealth accumulation in their account will be retarded by withdrawals from their account, including regular withdrawals of dividends.

Information contained herein is derived from various sources as set out in the narrative. Although we believe the information provided by the sources to be accurate, we have not independently verified the information.

Investors should consider the Fund's investment objectives, risks, charges and expenses carefully before investing. Investors may obtain a free prospectus which contains this and other information about the Fund by calling (800) 432-4789. Please read the prospectus carefully before investing.
